

Alpha Induces Cooperative Behavior ^[SEP]

Researchers studying the trembling of hands revealed that people who tremble in the theta range (4 to 8 Hz) tend to separate themselves from those around them and tend to feel victimized. Those in the Alpha range (8 to 13 Hz) tend to view themselves as in service to the group, and those trembling in the Beta range (13 to 20 Hz) tend to be overloaded with logistical, or dilemma-type, worries.

It is hypothesized that, since our bodies are made up of billions of cells that communicate with each other, including signals in the Alpha frequency range will move cells from a “victimized” or “overloaded” vibration into a state of group cooperation. This is supported by experiments in waiting rooms, which show that when an Infratonic device is left running in the room, patients are observed to be more cooperative.

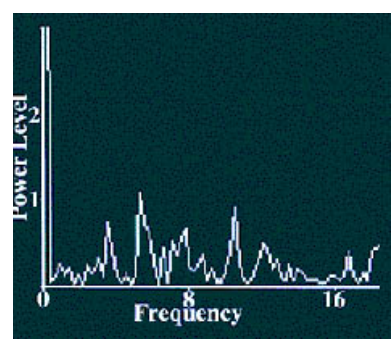

Chaos Therapy Calms Trembling ^[SEP] Research revealed that the advanced version with highly unpredictable signal within a narrow frequency range was far more effective than the early units at breaking up the Theta and Beta activity. This technology was based on the hypothesis that vibrational patterns of disease and disruption of communication reside in the body, and can be reduced with highly unpredictable signals in an adjacent frequency range.

Graph 1 shows a test subject trembling just before starting infratonic Therapy, with noise across the spectrum.

Graph 2 shows that after just three minutes of infratonic Therapy, the noise has decreased and is predominantly in the alpha range.

After two minutes of rest after therapy, Graph 3 shows that the noise has decreased even further, leaving the subject feeling calm, relaxed, and mentally clear.
